This email documents the completion of APT analysis of 6 of the samples from the 1st ORNL shipment of broken SSJ specimens to support CINR Project “MIT JL 18-1783 PIE (NSUF-1.2 HFEF)(PICS work package UA-22IN060502)”. The 6 samples that have been analyzed for APT are listed below. This effort fulfilled the requirements of the Level III milestone “MIT JL 18-14783 PIE: Complete APT testing on 1st set of ORNL provided specimens (6 specimens) (Zackrone)”.

IMCL ID#	Project ID#	Material	DPA	
IMCL-0286	M9S 13	Steel2	1.4 dpa	
IMCL-0290	M10S 01	Steel1+OC	0.7 dpa

- M4S 01 - Fe-20Cr-2Si (2.1 dpa)
- M4S 02 - Fe-20Cr-2Si (2.1 dpa)
- M4S 03 - Fe-20Cr-2Si (2.1 dpa)

Significant radiation embrittlement even at <1 dpa

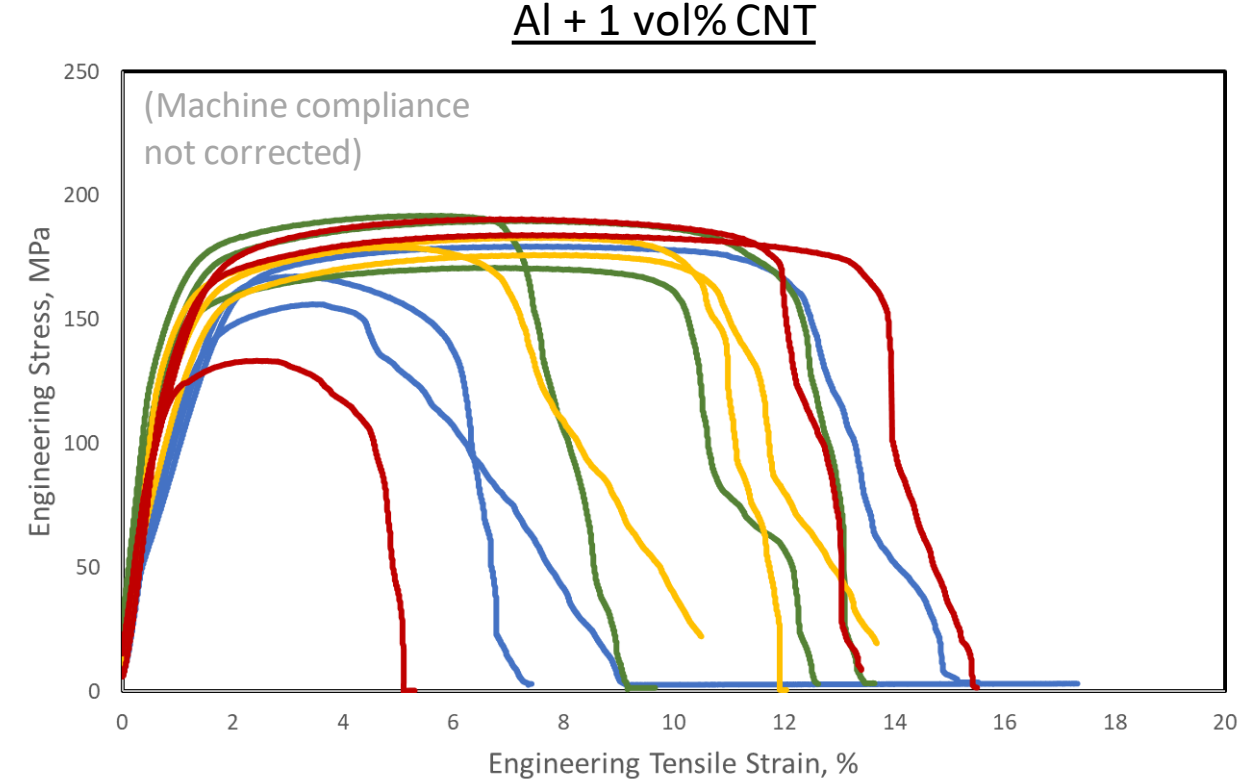

Single Crystal Ni

Tensile ductility decreased by a factor of > 2 upon irradiation but didn't change greatly with further increasing dpa

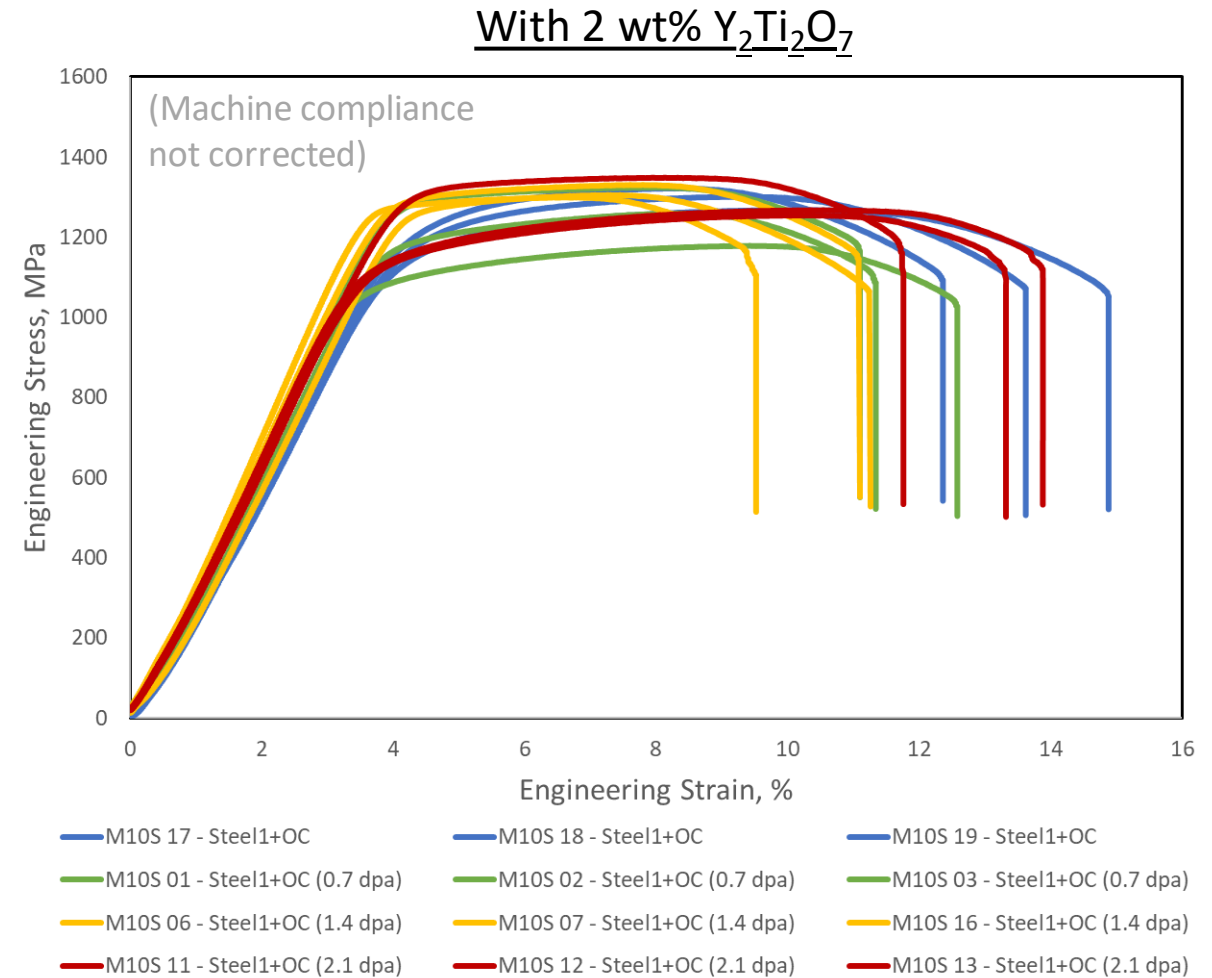

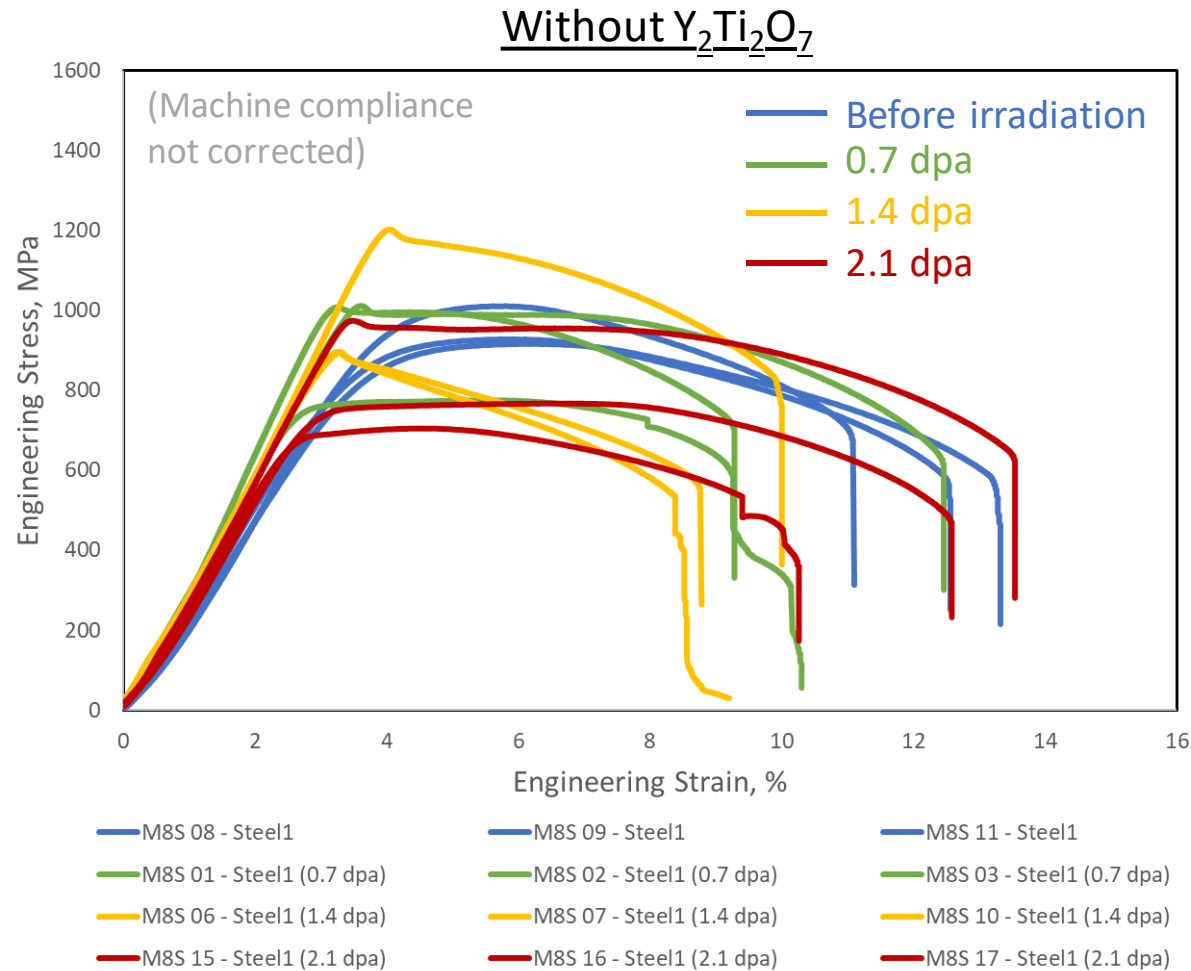

M1A 17 - Al M1A 18 - Al M1A 19 - Al M1A 01 - Al (0.7 dpa)
 M1A 02 - Al (0.7 dpa) M1A 03 - Al (0.7 dpa) M1A 06 - Al (1.4 dpa) M1A 07 - Al (1.4 dpa)
 M1A 16 - Al (1.4 dpa) M1A 11 - Al (2.1 dpa) M1A 12 - Al (2.1 dpa) M1A 13 - Al (2.1 dpa)

M2A 04 - Al+CNT M2A 06 - Al+CNT M2A 14 - Al+CNT
 M2A 07 - Al+CNT (0.7 dpa) M2A 08 - Al+CNT (0.7 dpa) M2A 09 - Al+CNT (0.7 dpa)
 M2A 12 - Al+CNT (1.4 dpa) M2A 13 - Al+CNT (1.4 dpa) M2A 15 - Al+CNT (1.4 dpa)
 M2A 01 - Al+CNT (2.1 dpa) M2A 02 - Al+CNT (2.1 dpa) M2A 03 - Al+CNT (2.1 dpa)

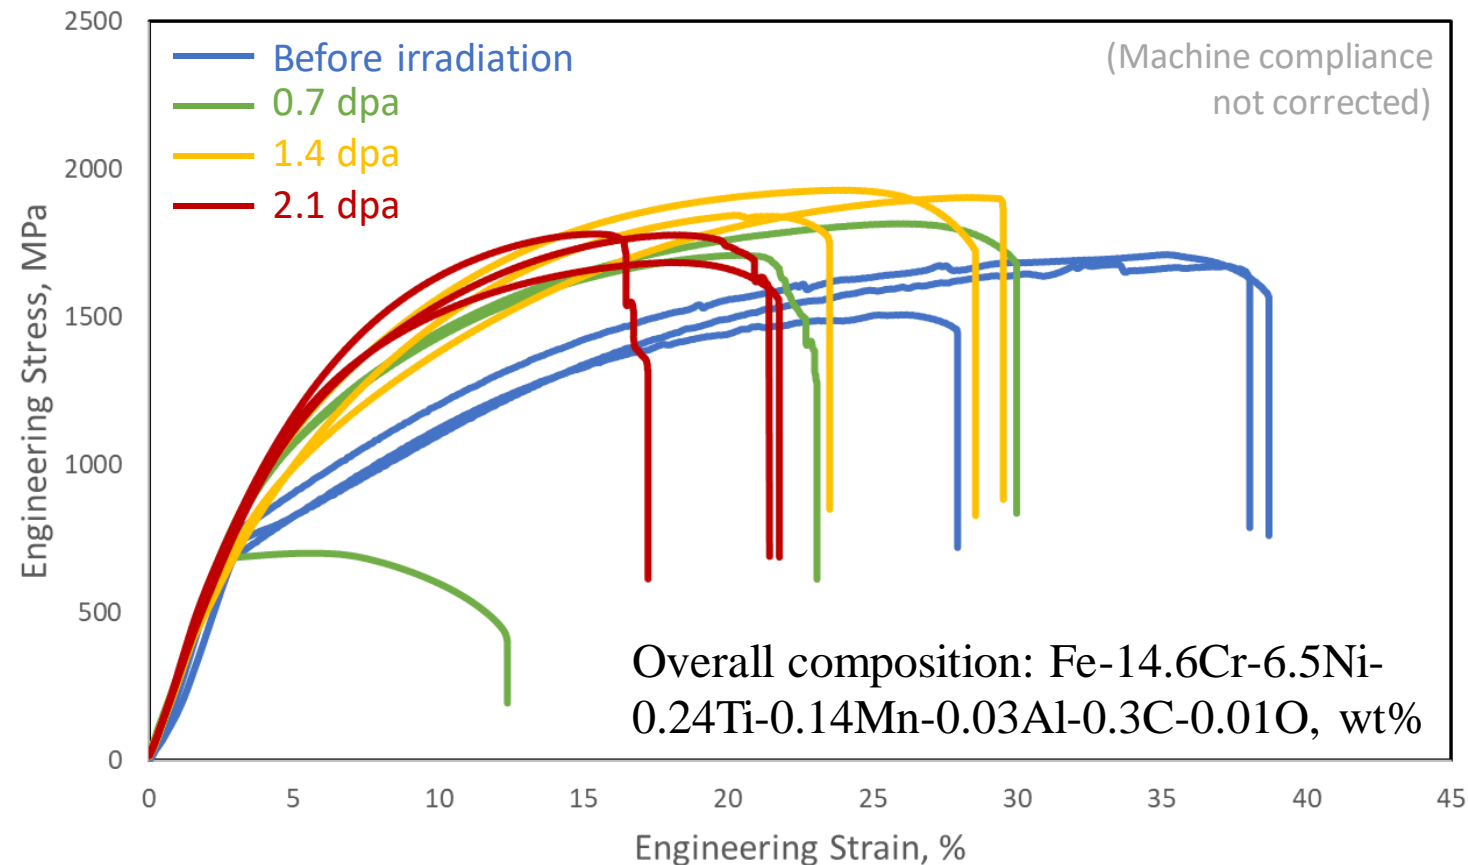

- Higher strength, but significant manufacturing variabilities
- Tensile ductility about the same
- No significant radiation embrittlement: low $T_M(\text{Al})=1000\text{K}$

9Cr-1W Steel (+ 2 wt% $\text{Y}_2\text{Ti}_2\text{O}_7$)

- Not large radiation embrittlement – F/M are intrinsically more radiation tolerant due to internal interfaces
 - The 2wt% YTO provides higher strength and ductility

15Cr-7Ni Steel + 1 vol% TiC

This sample had ~5% martensite before tensile tests and radiation

M11S 01 - Steel2+OC	M11S 02 - Steel2+OC	M11S 03 - Steel2+OC
M11S 08 - Steel2+OC (0.7 dpa)	M11S 09 - Steel2+OC (0.7 dpa)	M11S 10 - Steel2+OC (0.7 dpa)
M11S 13 - Steel2+OC (1.4 dpa)	M11S 14 - Steel2+OC (1.4 dpa)	M11S 19 - Steel2+OC (1.4 dpa)
M11S 04 - Steel2+OC (2.1 dpa)	M11S 05 - Steel2+OC (2.1 dpa)	M11S 06 - Steel2+OC (2.1 dpa)

Tensile ductility decreases with radiation but is still greater than that of 9Cr-1W steel with $Y_2Ti_2O_7$, and it also exhibits significant work hardening capability.

1.4 dpa, before deformation

Cr-rich near TiC (observed both before and after irradiation)

2.1 dpa, before deformation

Ti-rich particles other than TiC are present
(Not observed before irradiation)

Further exploration is needed regarding TiC fraction, composition, spatial distribution, etc.

15Cr-7Ni Steel + 1 vol% TiC

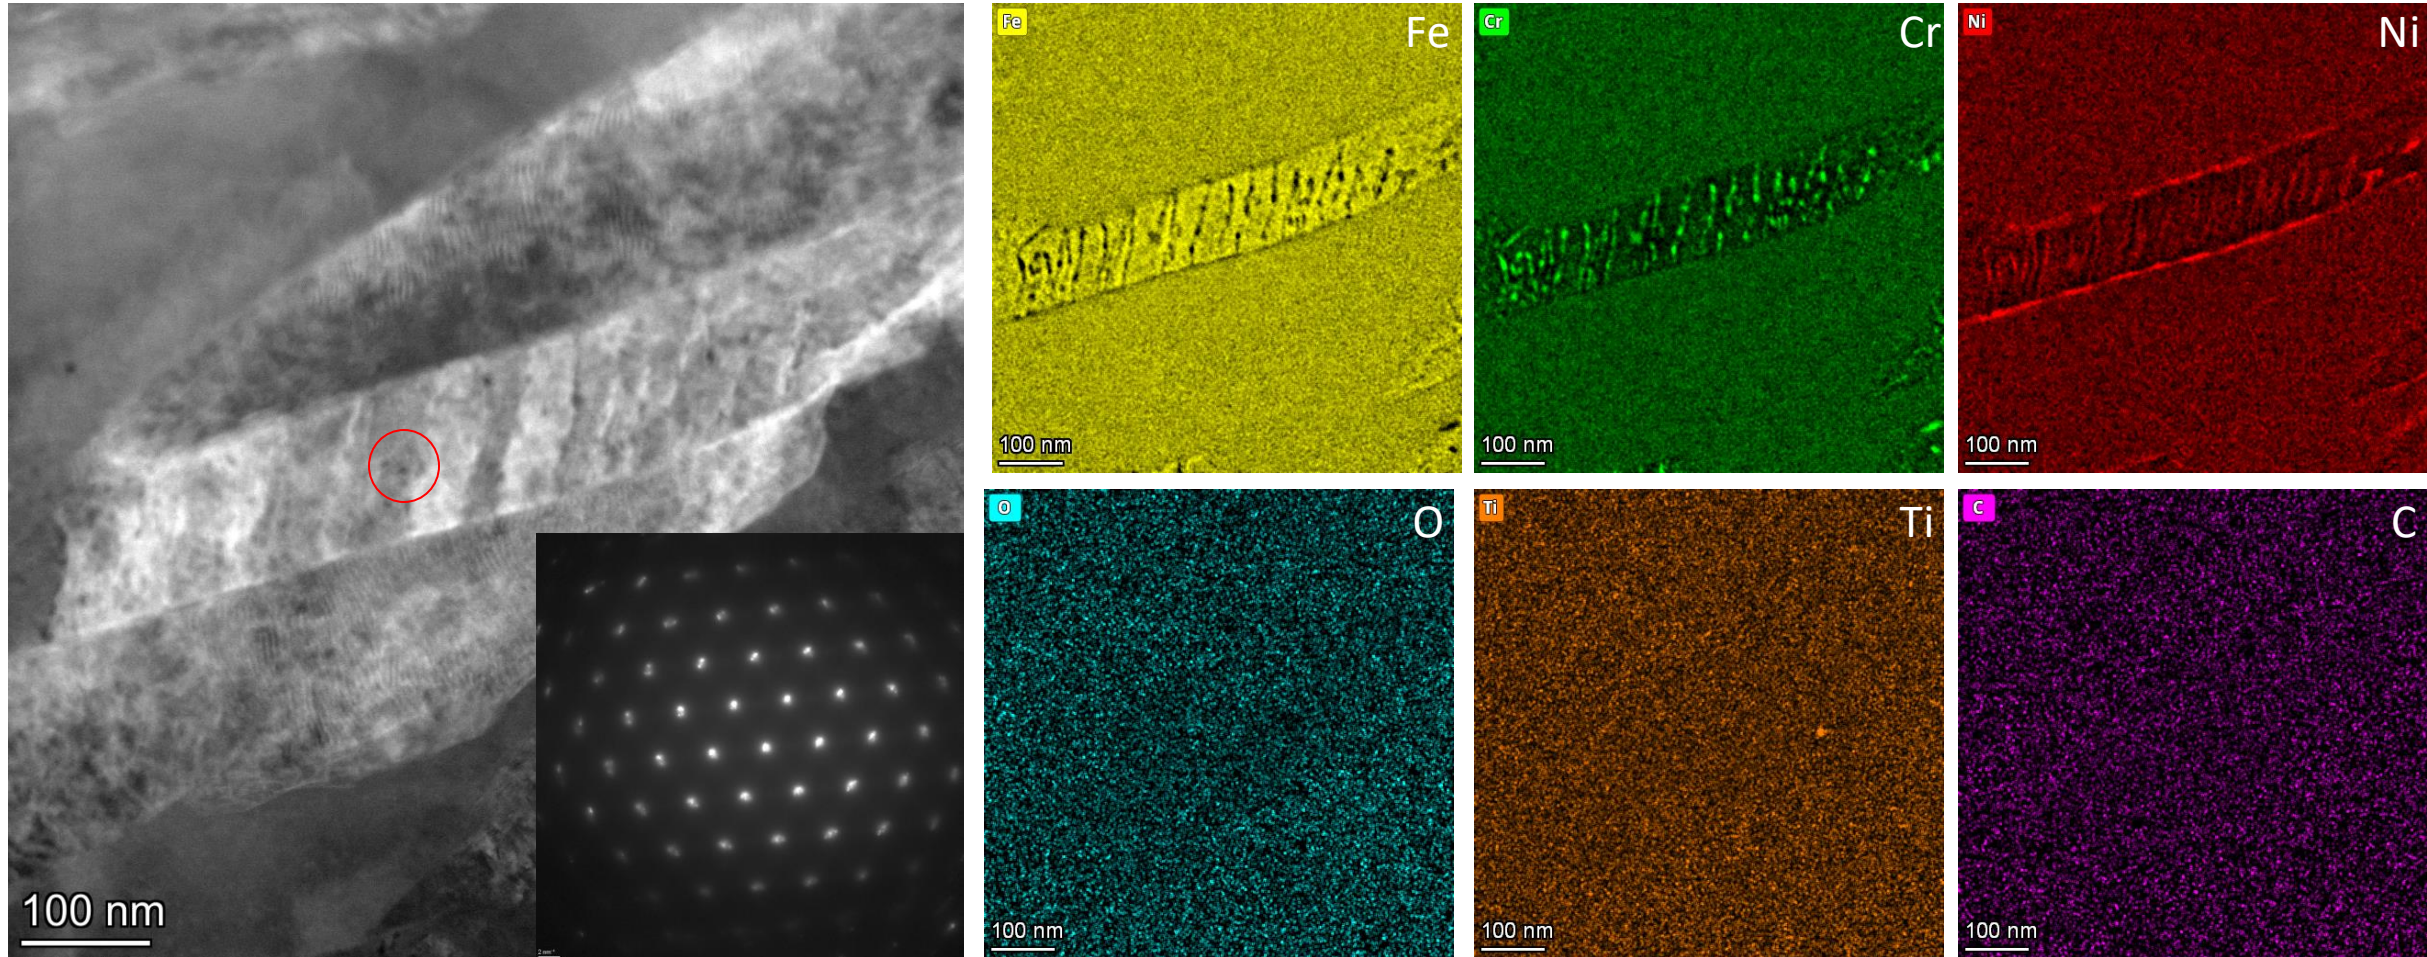

> 1 dpa, before deformation

Highly nanostructured, accompanied by the presence of martensite

15Cr-7Ni Steel + 1 vol% TiC

> 1 dpa, before deformation

Elemental segregation is observed in martensite after irradiation.

Such elemental segregation was not observed in an atom probe analysis of unirradiated specimens.

The segregation happened during radiation.

15Cr-7Ni Steel + 1 vol% TiC

> 1 dpa, before deformation

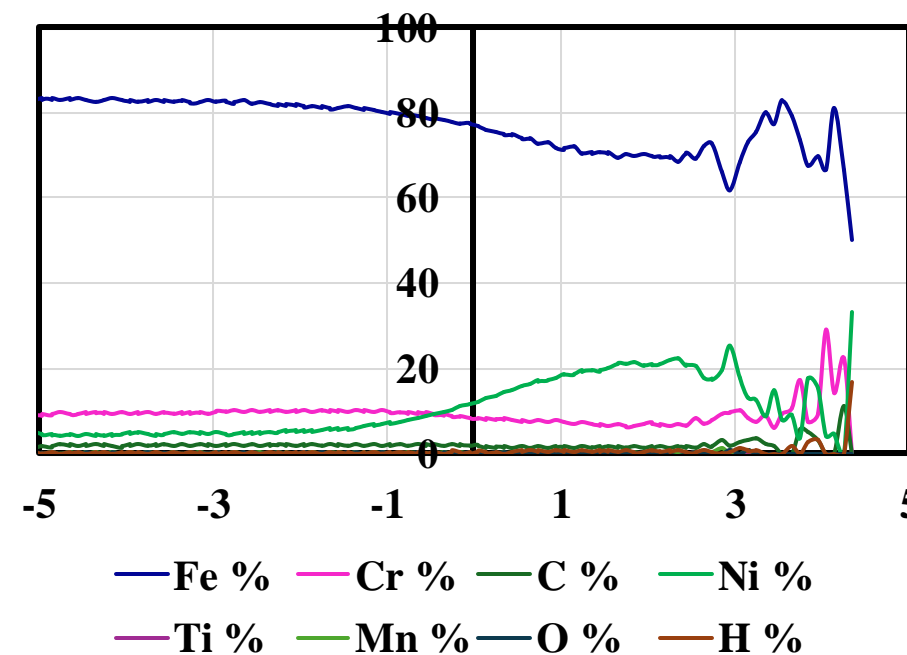

- Particle-like Cr-rich regions and **plate-like Ni-rich regions** were additionally observed.
- Correlations with the spatial distribution of other elements (e.g., O or C) were **not** clearly seen **at the nanoscale**.

Reconstruction no. R1194

Element	At. %	Sigma %
Fe	84.01	0.01
Cr	8.88	0.00
C	1.27	0.00
Ni	4.92	0.00
Ti	0.04	0.00
Mn	0.16	0.00
O	0.23	0.00
H	0.48	0.00

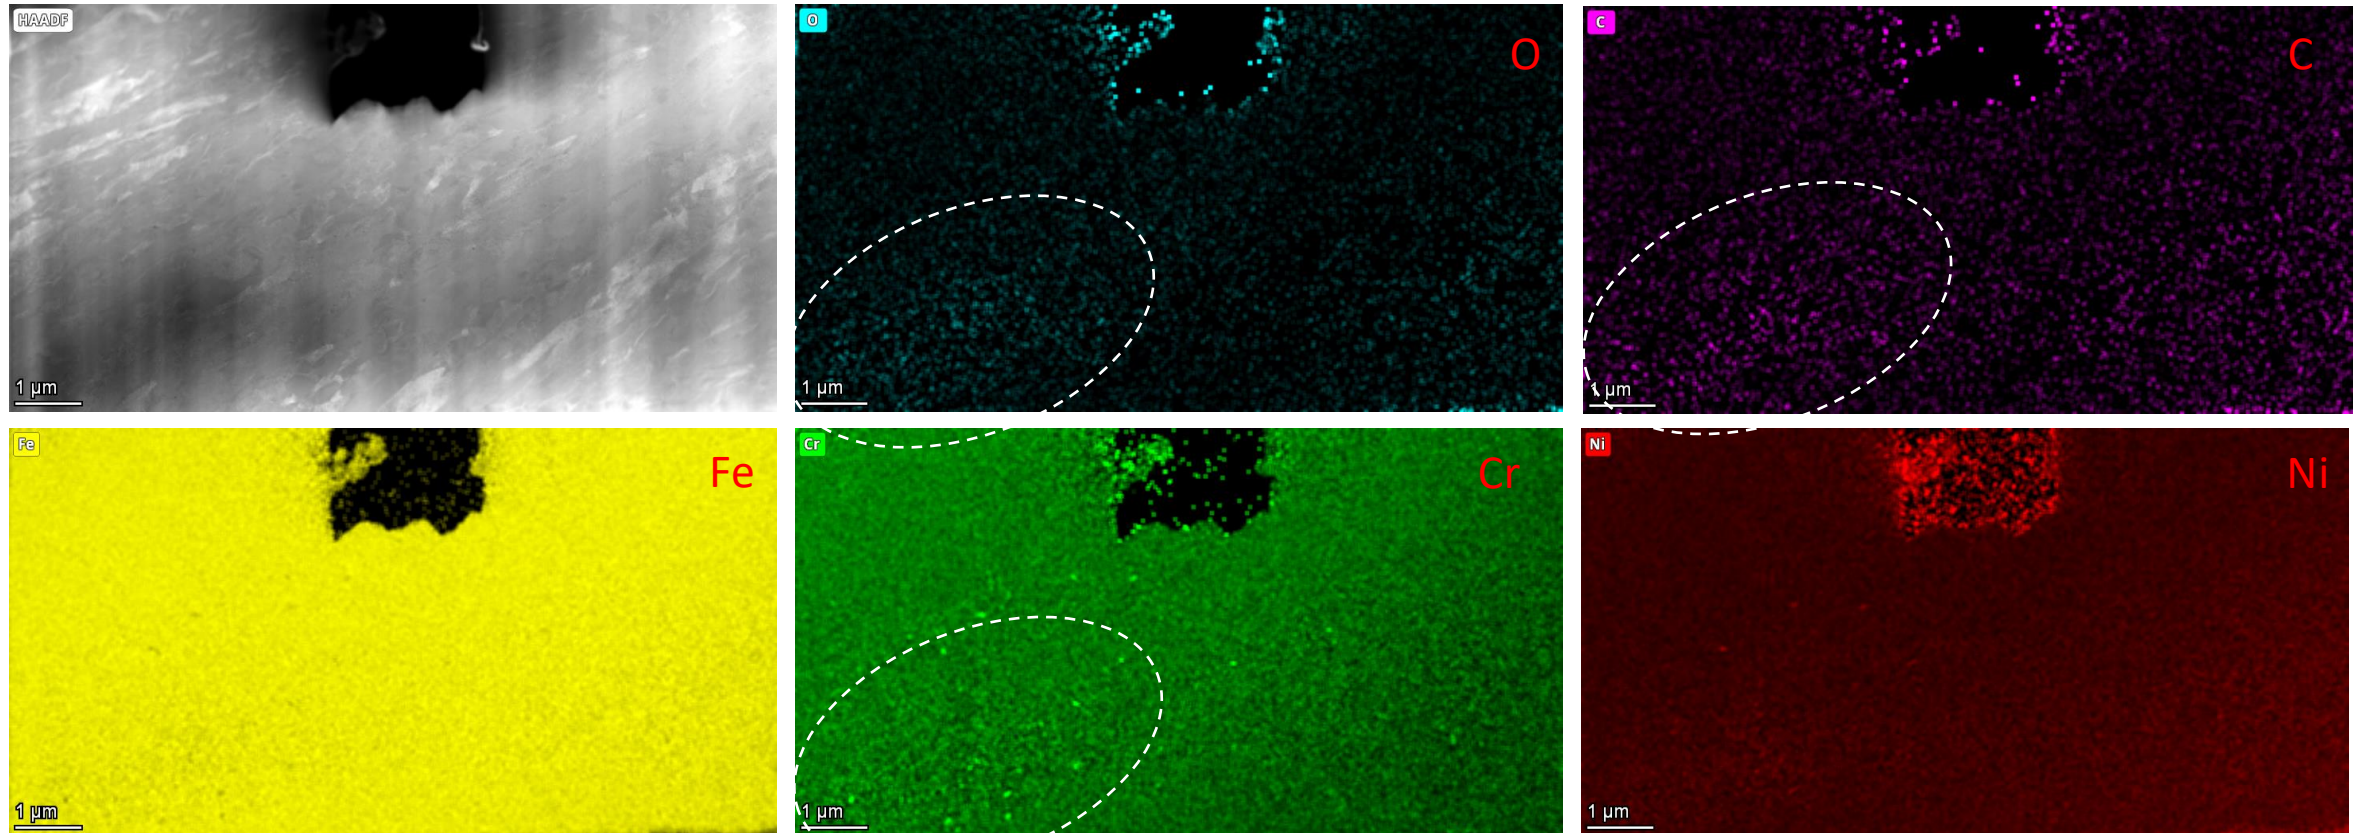

Bulk composition

Proxigram across Ni 1.2 at.% isosurface

Ni iso-surface 11.2 at.%

> 1 dpa, before deformation

That being said, oxygen and carbon contents were richer in regions exhibiting segregation at a larger scale.

15Cr-7Ni Steel + 1 vol% TiC

> 1 dpa, before deformation

Voids with a diameter of a few nanometers formed upon irradiation
This material, however, showed tolerance to radiation

(f) SAED pattern obtained from Cr and B rich region revealing the formation of **CrB₂** in LPBF-optimized In939+TiB₂.

EBSD grain size distribution and texture

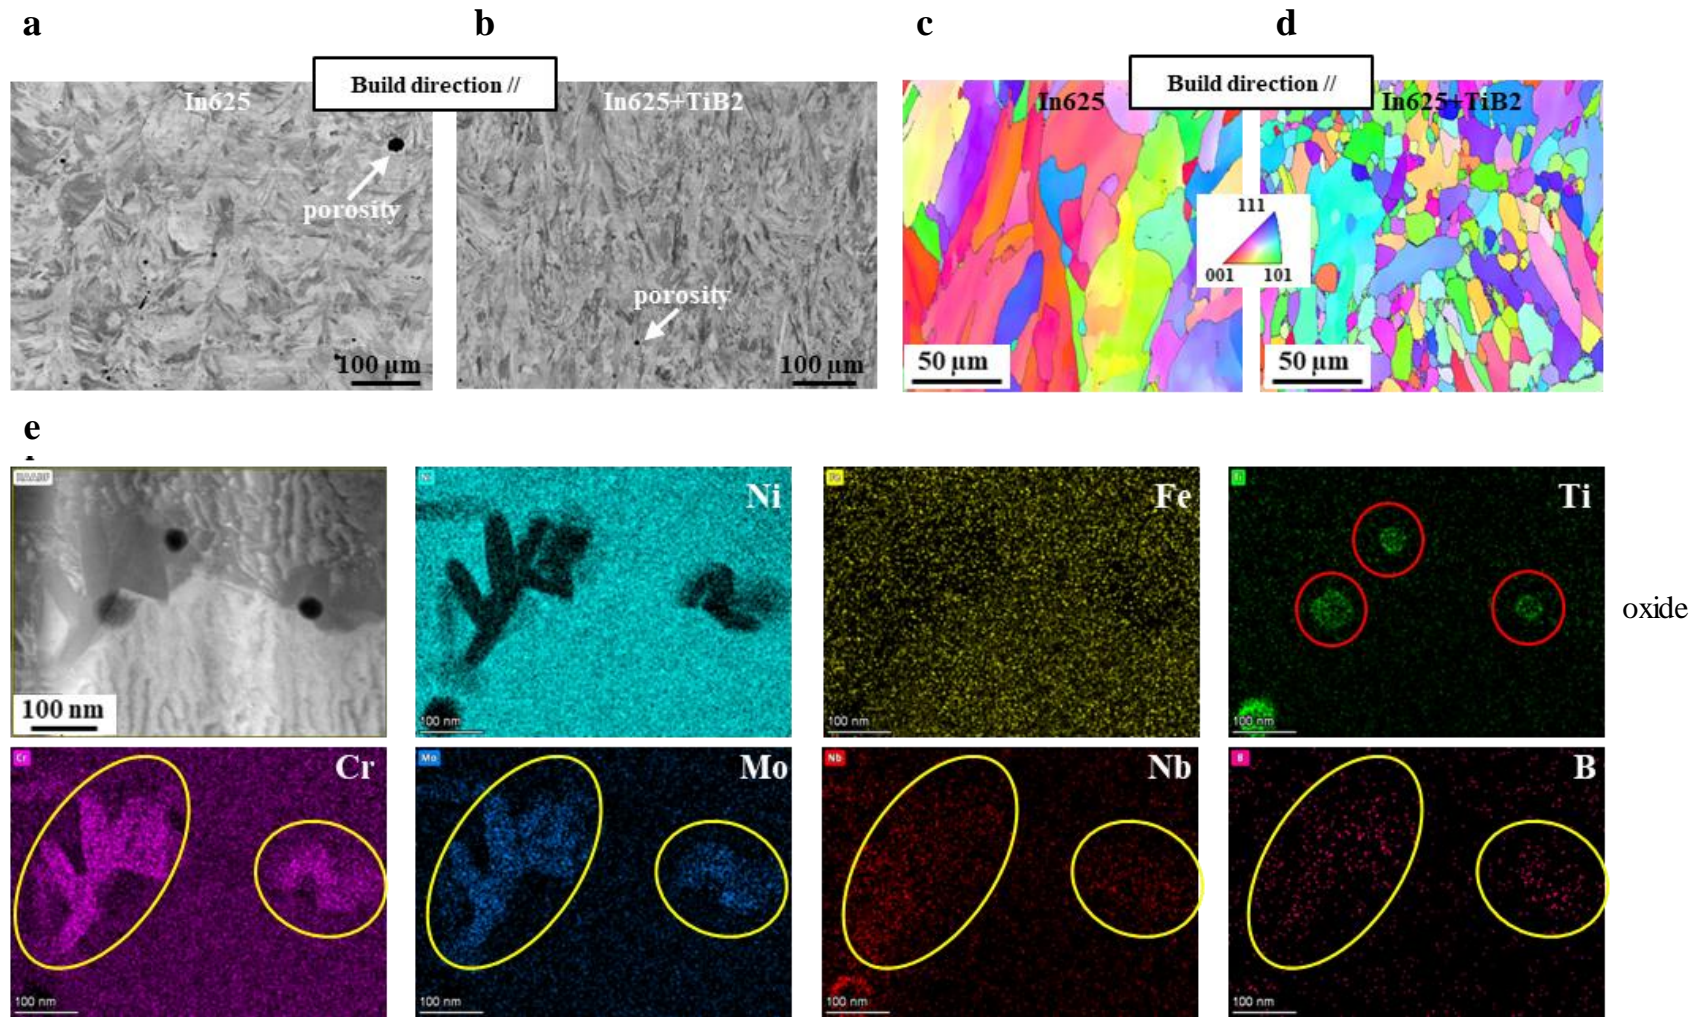

EBSD results obtained from LPBF-optimized In939 and In939+TiB₂: (a,b) inverse pole figure maps, (c,d) pole figures (PF), (e,f) Kernel average misorientation maps (KAM), and (g) grain size distribution plot. Please note that the equiaxed fine grains are highlighted within white dashed regions.

Pure In939: Carbides and oxides exist in the vicinity of long cracks. Furthermore, cracking propagates along GBs

(a,b) SEM/EDX analysis focusing on cracking region, please note that Ti-, Nb-, Ta-based carbides and Al-based oxides indicated by red and yellow arrows. (c-f) inverse pole figure maps obtained from cracking zones.

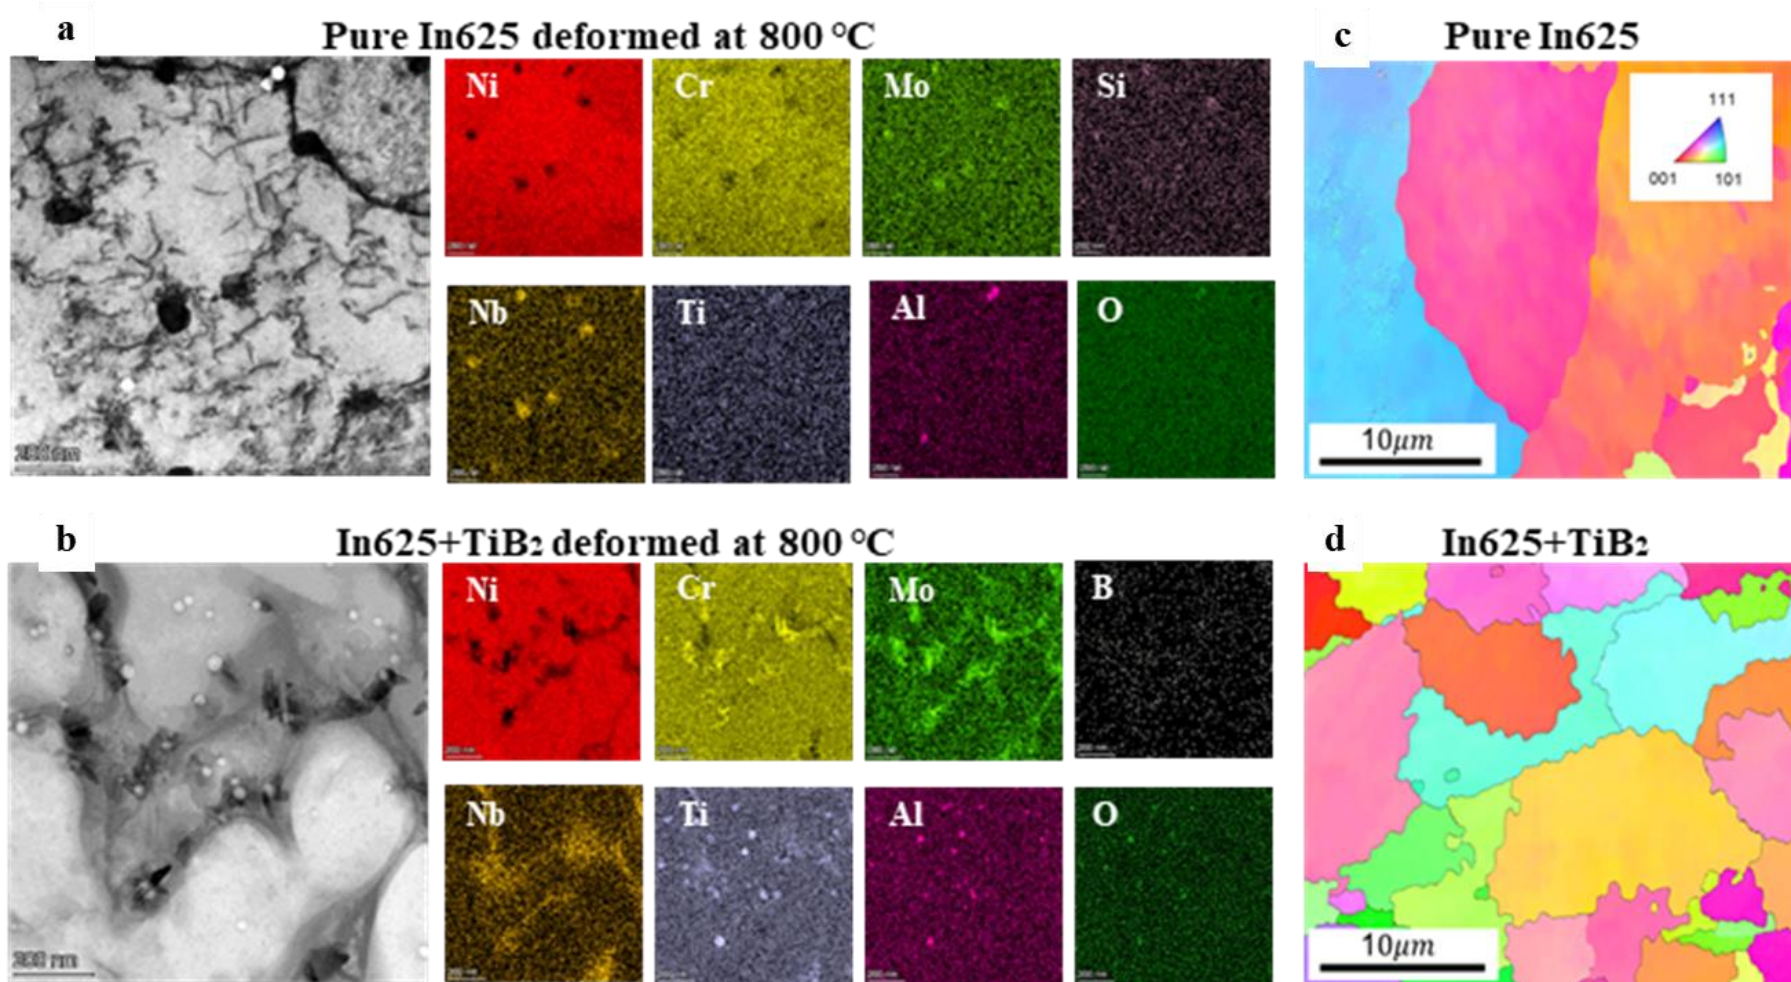

Microstructural properties of as-printed specimens

(a-d) SEM images obtained from In625 and In625+TiB₂, (g-h) EBSD orientation maps obtained from In625 and In625+TiB₂ revealing the reduction in grain size, (e) STEM/EDX mapping micrographs obtained from In625+TiB₂ shows the exchange reaction zone between **Cr**, **Mo**, **Nb**, Ti, and B.

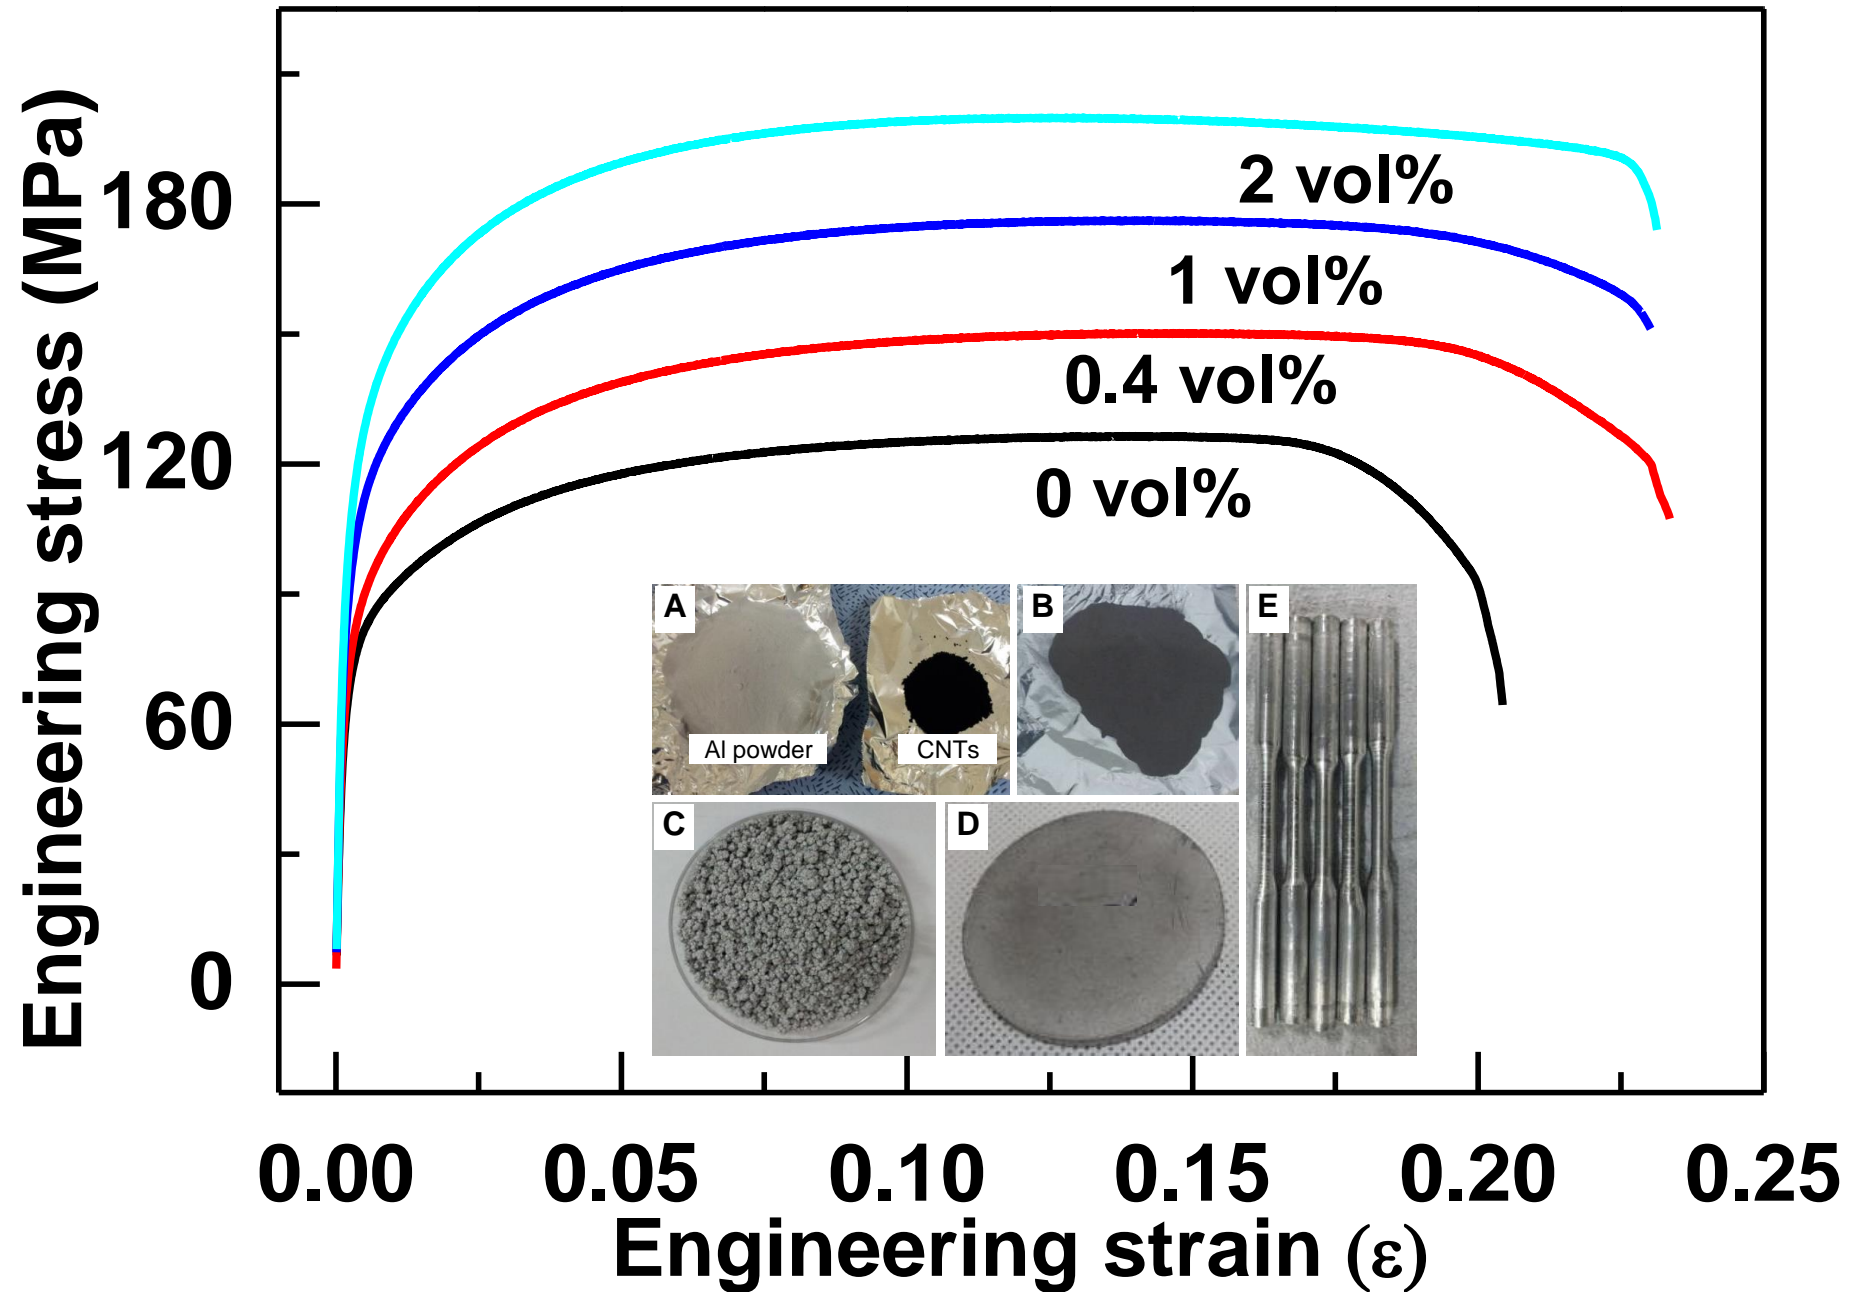

Deformed In625+TiB₂ at 800 °C

(Collaboration with Prof. Gi-Dong Sim at KAIST)

(a) BF-TEM image and STEM-EDS map of deformed In625 and (b) In625+TiB₂; (c) Characteristics of grain boundaries in pure In625 and (d) In625+TiB₂ as confirmed through IPF maps.

Aluminum-Carbon Nanotube Composites

100keV He ion, fluence $10^{17}/\text{cm}^2$, peak dose 3.5 DPA

Nano Energy

Adding “2D” graphene was not beneficial to strength or ductility or radiation tolerance
(mislabeling of dpa may have occurred?)

1000 appm = 0.1 at% doesn't sound like a lot – but Helium goes to GBs

Helium-storing 2nd phases?

**Use low- E_{embed} phase to shield/protect
higher- E_{embed} phase GBs**

H-W. Xu†, S.Y. Kim†, D. Chen, J-P. Monchoux, T. Voisin, C. Sun* and J. Li*,
"Materials Genomics Search for Possible Helium-Absorbing Nano-Phases in
Fusion Structural Materials," *Advanced Science* **9** (2022) 2203555.

Helium Embedding Energy dictates Damage Location?

Half-Heusler alloy

Inspired by the discussion with Prof. Greg Olson

Helium Absorption and Damage Avoidance

Ti-48Al-2W-0.08B (at%) with a γ - α_2 nano-lamellar structure

Helium ion
implantation
(up to 1 at%
at 750°C)

Helium bubbles formed mostly in α_2 phase without noticeable interfacial segregation, leaving γ phase almost intact.

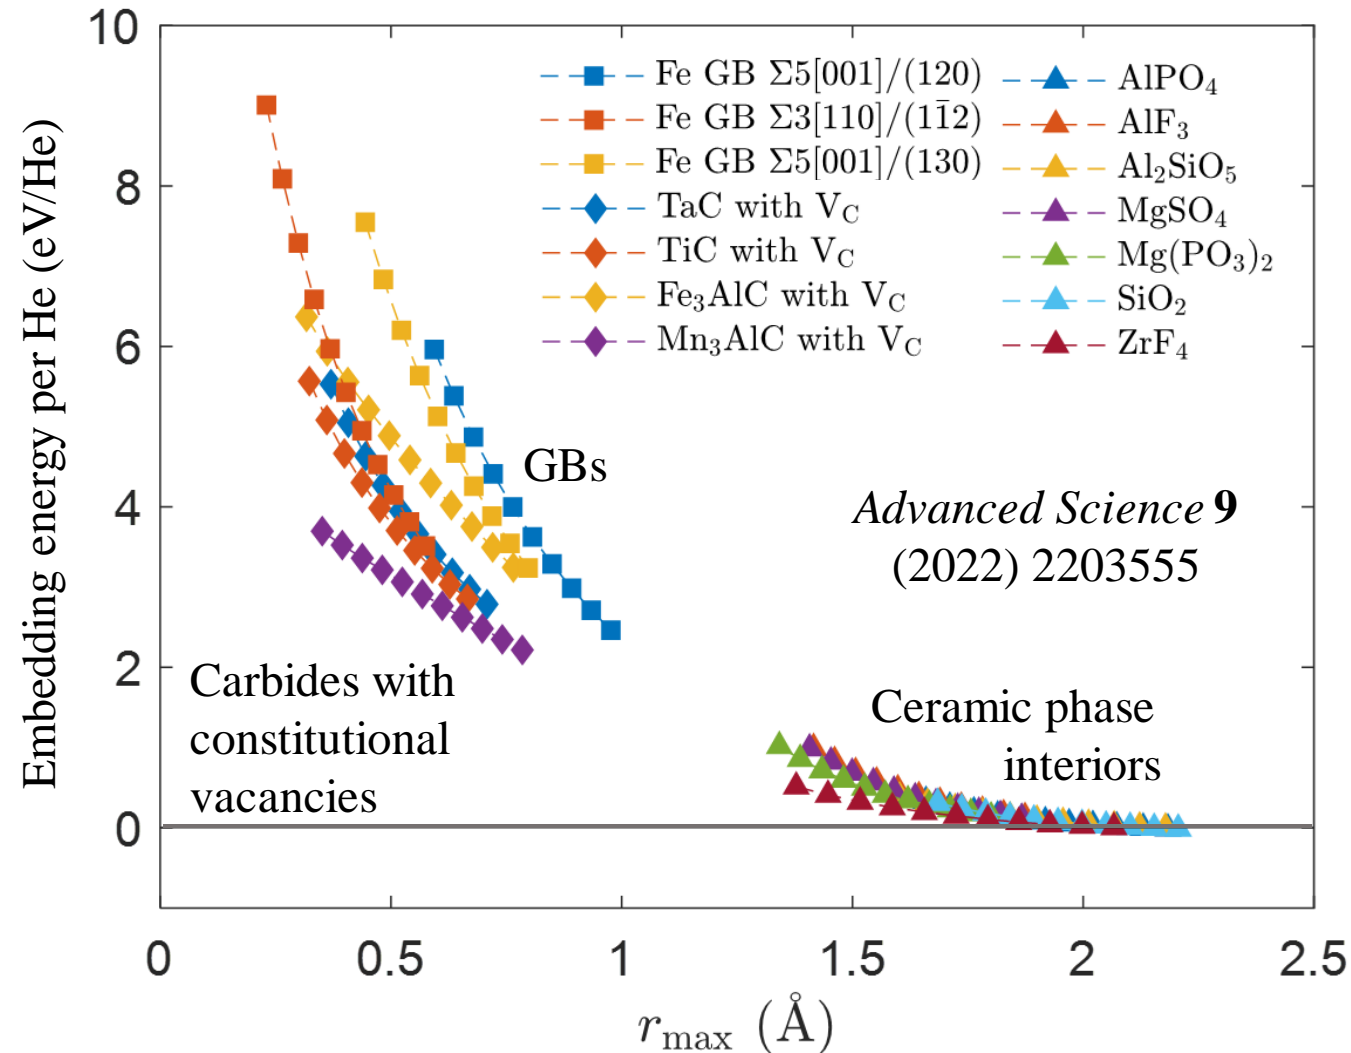

\mathcal{E}_{emb} : Energy Required to Embed a Helium Atom

“Easier to embed helium”

$\Delta\mathcal{E}_{\text{emb}} \geq 0.5 \text{ eV/He}$ enough to enable preferential helium absorption strategy,
similar to Fe-GB versus Fe-lattice.

ϵ_{emb} Correlates with the “Atomic Free Volume”

Atomic-scale free volume is indeed a reliable indicator of low helium embedding energy.

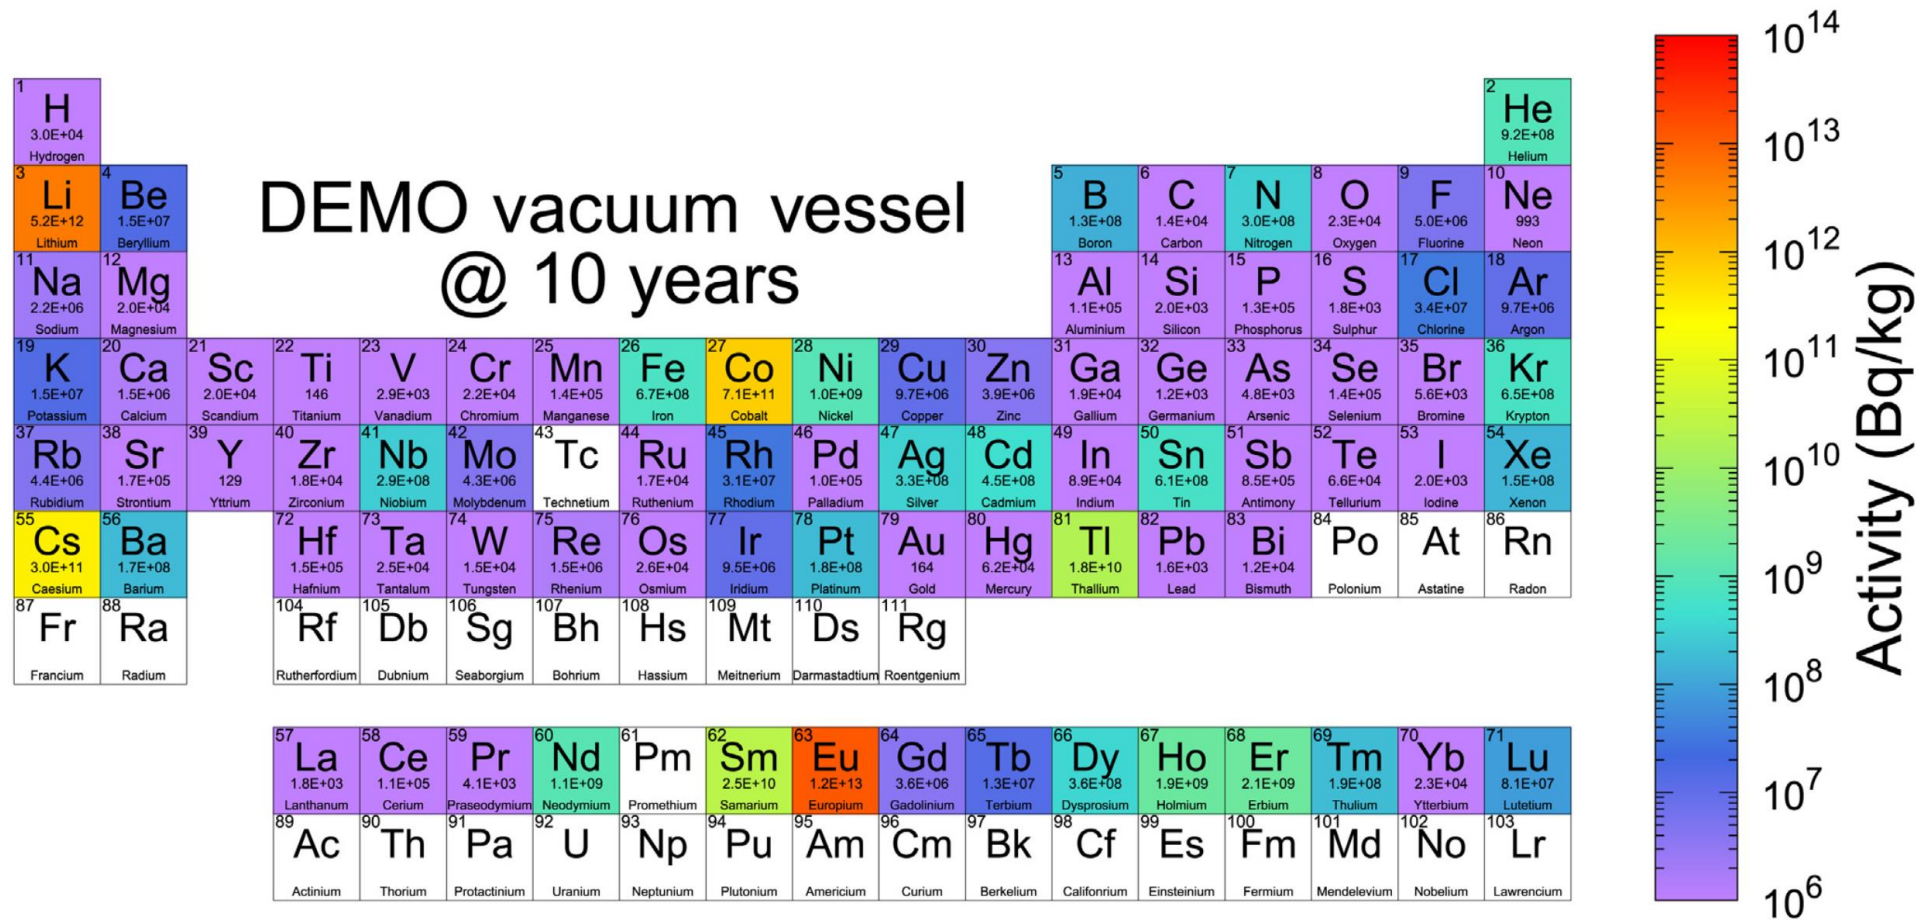

Fig. 10. Periodic table showing the total becquerel activity from each element after 10 years of decay cooling following a 2-fpy irradiation in a DEMO vacuum vessel (VV) environment. The colour of each element reflects the activity according to the Bq/kg legend, but the absolute values are also given beneath each element symbol.

Mark R. Gilbert, Michael Fleming, Jean-Christophe Sublet, “Automated inventory and material science scoping calculations under fission and fusion conditions”, *Nuclear Engineering and Technology* **49** (2017) 1346

Screening of Helide Forming Phases

Helium absorbing capability

- Atomic-scale free volume, r_{\max} (the radius of the largest sphere that can be fitted in crystal structures) $\geq 1.5 \text{ \AA}$

Neutron friendliness

- Neutron absorption cross-section < 1 barn
- Neutron activity $< 10^2$ MBq/kg 10 years after shutdown

Mechanical robustness

- Bulk modulus > 50 GPa
- Shear modulus > 20 GPa

Formula	Materials Project ID	r_{\max} (Å)	Average Bulk Modulus (GPa)	Average Shear Modulus (GPa)
$\text{Ca}_{72}\text{P}_{48}\text{O}_{192}$	1197377	1.74	91.71	57.69
$\text{P}_{24}\text{Pb}_{12}\text{O}_{84}$	1203776	1.62	87.50	39.50
$\text{Mg}_{10}\text{C}_8\text{O}_{36}$	1204170	2.21	79.84	40.81
$\text{O}_{144}\text{Al}_{48}\text{Ca}_{72}$	12147	1.63	96.55	64.65
$\text{Ca}_2\text{H}_8\text{S}_2\text{O}_{12}$	23690	1.62	80.74	40.69
$\text{Bi}_2\text{P}_8\text{H}_2\text{O}_{24}$	24348	1.81	92.20	43.35
$\text{Zr}_4\text{P}_4\text{O}_{18}$	27132	1.61	132.31	71.18
$\text{Bi}_4\text{P}_{12}\text{O}_{36}$	27135	1.70	98.13	47.84
$\text{P}_8\text{H}_{32}\text{O}_{36}$	27141	1.64	83.92	43.67

$\text{Na}_8\text{Si}_4\text{H}_{64}\text{O}_{44}$	504605	1.71	74.20	44.55
$\text{Al}_6\text{P}_{18}\text{O}_{54}$	540549	1.63	117.80	65.63

~750 candidate phases were identified (mostly oxides or fluorides).

Ceramic – Molten Metal Contact Angle $< 90^\circ$

```
The first step is to specify the type of estimation and machine learning model you would like to use.
Enter type (1: one metal-one ceramic pair; 2: one metal-list of ceramics; 3: ICSD screening): 2
Enter model (all: model trained using all features; reduced: model trained using a reduced number of features): all
=====
The second step is to specify the systems of interest.
Note that this code is case sensitive. You need to enter "Fe" for iron; "fe" does not work.
Also, you need to enter "SiO2" for silicon dioxide; "SiO2" does not work.
Enter the metal of interest (e.g., Fe): Li
Upload the csv file with the list of ceramics to the session storage and enter the filename (e.g., filename.csv): lists.csv
Enter the header of the list of ceramics (e.g., ceramic): comp
=====
The third step is to specify the temperature range of interest.
Enter the temperature of interest in Kelvin in the format, "min max interval (e.g., 1800-1800-0 or 1800-2300-100)": 500-500-0
=====
```

- The wettability of CaO by molten Li
 - Machine learning model: 119.5°
 - *Ab initio* molecular dynamics

test.csv			
31 to 40 of 48 entries			
	Metal	Substrate	Temp
			theta_pred
30	Li	CaO	500.0
31	Li	Pr2O3	500.0
32	Li	La2O3	500.0
33	Li	Nal	500.0
34	Li	Ac2O3	500.0
	Li	YbO	500.0
	Li	Bal2	500.0
	Li	CaH2	500.0
	Li	Er2O2S	500.0
	Li	Ho2O2S	500.0

Down-Selection of Helide-Forming Phases

- Melting point > 1600 °C for casting
- Phase compatibility: no decomposition when in contact with the matrix
- Interfacial wetting and adhesion: ideally, contact angle less than 90°

Matrix: Fe

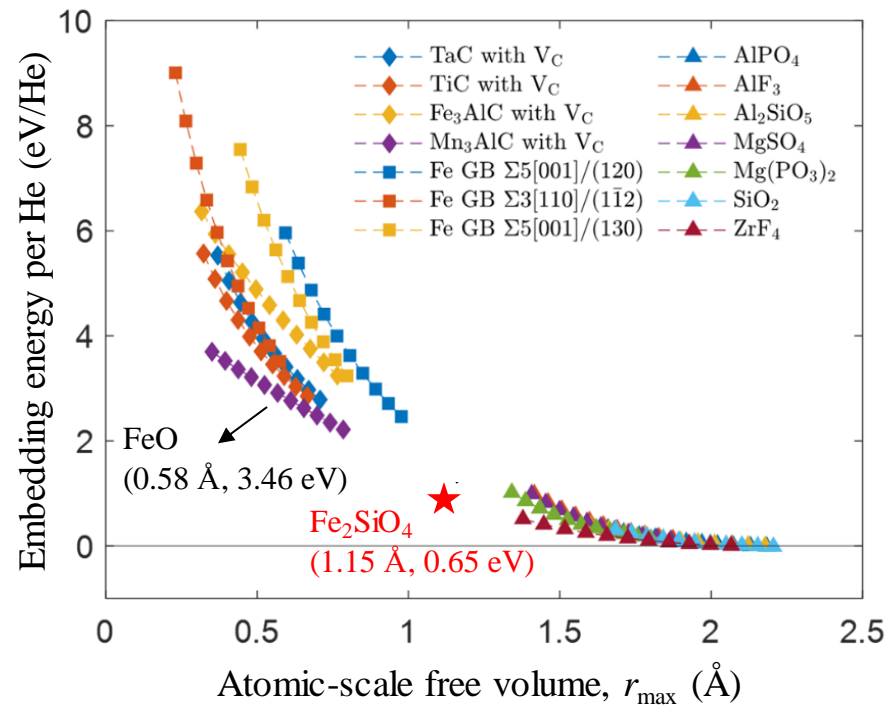

Chemical formula	Material project ID	Avg. bulk modulus (GPa)	Avg. shear modulus (GPa)	r_{\max} (Å)	Contact angle at 1600 °C (deg.)	Melting point (°C)	Phases at 800 °C for Fe with 1 wt.% of He-absorbing nano-phase
Al ₂ SiO ₅	mp-4753	155.8	97.5	1.90			×
AlPO ₄	mp-7848	84.6	48.2	1.92			×
SiO ₂	mp-546794	93.8	57.5	1.93			
AlF ₃	mp-468	116.1	53.0	1.64		×	
Mg(PO ₃) ₂	mp-18620	113.5	60.8	1.57			×
MgSO ₄	mp-4967	106.8	51.5	1.64			×
ZrF ₄	mp-561384	133.4	54.7	1.73		×	

- Decomposition products could also be useful if they have large free volume.
- Less strict atomic-scale free volume criterion (e.g., $r_{\max} > 1 \text{ Å}$) could also be enough.

Composite Design

Ab initio computed XRD patterns

DFT: VASP (GGA-PBE, PAW & plane-wave basis func.) | CALPHAD: ThermoCalc (TCFE8)

S.Y. Kim et al. "Demonstration of Helide Formation for Fusion Structural Materials as Natural Sinks for Helium," *Acta Materialia* **266** (2024).

Experiment Design

Helium ion implantation

Grazing incidence XRD (GIXRD)

- X-ray incident angle: 1°

Fe_2SiO_4 to helium ratio = 1:1 ($\text{Fe}_2\text{SiO}_4 \cdot \text{He}$, ~ 10 at% uptake)

Experimental vs. Computed XRD Patterns

Computed XRD patterns

Experimental XRD patterns

- Peaks related to Fe_2SiO_4 : P-1, P-2, P-3, and P-4.
- In both patterns, P-1 and P-4 decrease. P-2 almost disappears, while P-3 sharpens; this agreement **confirms atomic helium storage** within the **bulk lattice of Fe_2SiO_4** .

Helium Bubbles Accumulation

5,000 appm (practical requirements: 1,000-2,000 appm)

$$d = 4.7 \pm 0.8 \text{ nm}; n = 1.67 \times 10^{22}/\text{m}^3$$

$$d = 3.6 \pm 0.7 \text{ nm}; n = 8.01 \times 10^{21}/\text{m}^3$$

Incorporation of helide formers by ~1 vol% can reduce the diameter (d) and the number density (n) of helium bubbles by > 20% and > 50%, respectively.

Estimation of the Required Volume Fraction

J. Knaster et al., *Nature Physics* **12** (2016) 424

Poster E-26
(Today @5:30 PM,
Hyatt-Regency R)

So Yeon Kim
@ Li Group

One helium atom per molecule (e.g., $\text{Fe}_2\text{SiO}_4 \cdot \text{He}$)
→ 0.1–0.2 mol% of 2nd phase could be enough (roughly ≤ 2 vol%)

Neutron irradiation of boron-doping materials

- Excess helium production by $^{10}\text{B}(\text{n}, \alpha)^7\text{Li}$ reaction
 - $^{10}_5\text{B} + \text{n}_{\text{th}} \rightarrow ^4_2\text{He}^{2+} + ^7_3\text{Li}^{3+}$ ($\text{KE}_{\text{He}} = 1.470 \text{ MeV}$, $\text{KE}_{\text{Li}} = 0.840 \text{ MeV}$)

reaction cross-section **3980 barn**

MITR 3GV port: thermal neutron flux as high as $10^{13} \text{ n}_{\text{th}}/\text{cm}^2/\text{s}$

Unlike **Boron-10** with a gigantic thermal neutron capture cross-section of **3980 barn**,
Boron-11 has a thermal neutron capture cross-section of only **0.005 barn**

Yunsong Jung and Ju Li, "Boron-10 stimulated helium production and accelerated radiation displacements for rapid development of fusion structural materials," *Journal of Materiomics* **10** (2024) 377-385

Helium generation and radiation damage of ¹⁰B-doped Fe and W irradiated at HFIR for 25 days.

Material	Dopant concentration (appm)		He generation (appm)	Radiation damage (dpa)			He appm/dpa
	¹⁰ B	²³⁵ U		Neutron (>0.1 MeV)	¹⁰ B(n, α) ⁷ Li	Fission reaction	
Fe	1,000	0	1,000	1.9	0.300	0	455.0
	1,000	1,000				10.0	82.0
	1,000	9,600				98.0	10.0
W	13	0	13	0.8	0.001	0	16.0
	13	13				0.1	14.0
	13	4,000				25.0	0.5

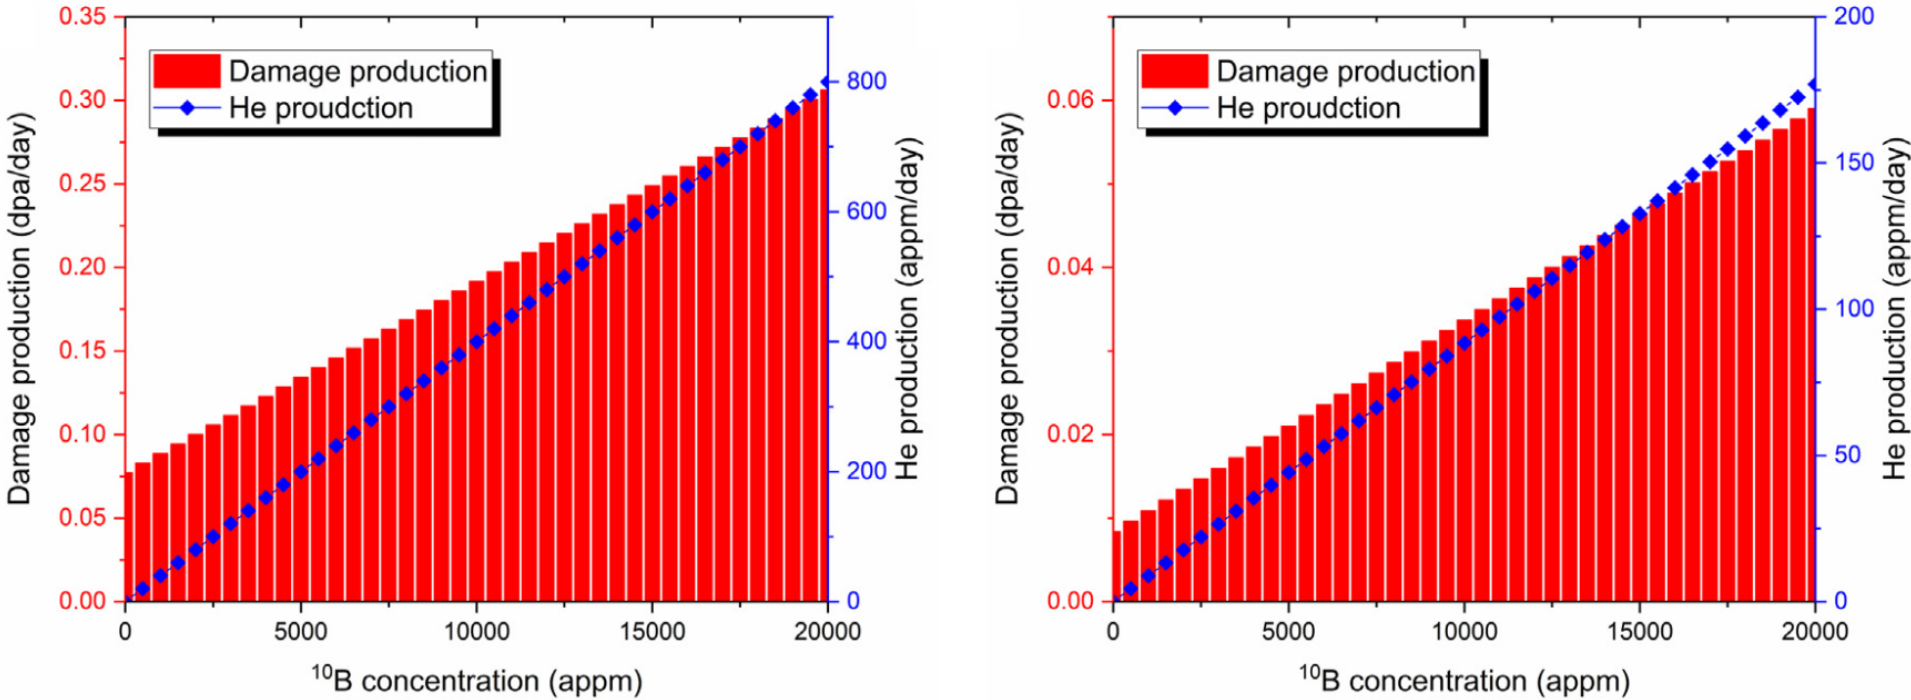

Fig. 7. Radiation damage production and helium production of iron doped with various ¹⁰B (a) neutron irradiation at HFIR (the half-life of burnt ¹⁰B was ~0.9 days) (b) neutron irradiation at MITR (the half-life of burnt ¹⁰B was ~61.4 days).

Yunsong Jung and Ju Li,
 “Boron-10 stimulated helium production and
 accelerated radiation displacements for rapid
 development of fusion structural materials,”
J. Materiomics **10** (2024) 377

Even a **boride particle** is likely to fragment into “bomblets”, due to the extreme energetic nature of the $^{10}\text{B}(\text{n}, \text{a})^7\text{Li}$ product nuclei and the **Coulomb explosion** of the electron cloud left behind. Thus later on, the distribution of the dpa and appm (He) could become much more homogenized due to the “**nano-bomblets**” effect.
